The incoming line to the distribution box is connected to neutral and ground

Overview

White: The neutral wire, responsible for sending unused electricity back into the breaker panel. When this MCB is turned on all other MCBs will get the power supply. For special loads sometimes double pole MCBs are used. Your breaker box wiring includes three main wire types: black hot wires carry electricity to outlets, white neutral wires return unused power, and green ground wires prevent electrocution. Ground faults occur when a hot wire touches a ground wire or metal box, creating a dangerous surge that trips. Confusion often arises when connecting the neutral and ground conductors within a breaker box, as their proper handling depends entirely on the panel's location within the electrical system. These two conductors serve fundamentally different safety functions, even though they may sometimes connect. The main reason for the confusion between Ground vs Neutral is because, the Neutral Wire is connected to Ground (Earth) at the transformer (which is the source) and also at the main circuit breaker panel on the consumer side (which is the load). The reason for this connection is to make the Neutral. The phase and neutral lines from the energy meter are connected to the main isolator.
